       Selection. ExtendMode = False 'end extend selection so next find won't change selection
       currentSectionText . Selection.Text 'put section text into a string to be manipulated
       This next routine looks through the current section text, which is selected at this
       point, and embeds HTML links to any any sections referenced between braces, i.e. I, or
       A, etc. It will do this by copying the selection into a string variable and searching
       for occurances of begLink and endLink, currently:
       "" - any single character - "". The "" and "" characters replaced the "<" and ">" '***
       characters in the mass replacements routine to not conflict with embedded html tags.
       The single character between the braces will be used along with currentSection$ to
       pull the target fifename and section name out of the Link Map and Document Map arrays.
       This action will be repeated until no more ? strings are found.
       Processing will then proceed with the next section, etc.
       Note that references that return a file named *.art will be handled specially since
       this is where the GIF thumbnail and link to the JPEG picture is inserted
                                               'needed a shorter name to work with
